AB The invention relates to graft copolymers, their preparation, and compns., such as electrophoresis separation media, containing the same; also to ultra-high mol. weight poly(N,N-dimethylacrylamide) polymers, their preparation, and compns., such as electrophoresis separation media, containing the same; and more particularly to

supports, such as capillaries, containing these polymers and methods for separating biomols., especially polynucleotides, using **capillary electrophoresis**. The graft copolymers can be prepared by, e.g., grafting polyacrylamide units onto a poly(DMA) backbone. Separation media comprising such graft copolymers or ultra-high mol. weight poly(DMA) polymers yield superior performance in the anal. and separation of biomols. by **capillary electrophoresis**.

AB The invention concerns devices, compns. and methods for performing **capillary electrophoresis** using a composition comprising in combination in an aqueous buffered medium a coating polymer and a sieving polymer, where the sieving polymer is more hydrophilic than the coating polymer and is present in greater amount Of particular interest are uncrosslinked **acrylamide** polymer mixts. for coating plastic channels and providing sieving for performing DNA sepns. in microfluidic devices. Polyacrylamide or N,N-di-Me **acrylamide** is used with a N,N-dialkyl **acrylamide** copolymer, either sep. or together for sieving and coating, serving as the medium in **capillary electrophoresis** DNA sepns.

AB Copolymers of **acrylamide** (AM) and N,N-dimethylacrylamide (DMA) with AM to DMA molar ratios of 3:1, 2:1 and 1:1 and mol. wts. of about 2.2 MDa were synthesized. The polymers were tested as separation media in DNA sequencing anal. by **capillary electrophoresis** (CE).
The dynamic coating ability of polydimethylacrylamide (PDMA) and the hydrophilicity of polyacrylamide (PAM) have been successfully combined in these random copolymers. A separation efficiency of over 10 million theor. plates per m has been reached by using the bare capillaries without the addnl. polymer coating step. Under optimized separation conditions for longer read length DNA sequencing, the separation ability of the copolymers decreased

with decreasing AM to DMA molar ratio from 3:1, 2:1 and 1:1. In comparison with PAM, the copolymer with a 3:1 AM:DMA ratio showed a higher separation efficiency. By using a 2.5% w/v copolymer with 3:1 AM:DMA ratio, one base resolution of 0.55 up to 699 bases and 0.30 up to 963 bases have been achieved in about 80 min at ambient temps.

AB The present invention refers to the use of multiple gradients (of chemical denaturants, thermal denaturants and of porosity of the gel matrix) for the separation of DNA fragments, amplified by PCR, normal or carrying point mutations, by zone electrophoresis on gel slabs or by **capillary electrophoresis** in presence of viscous polymer solns. (linear or branched). Such method can be extended to the anal. of mutations in proteins and to the optimization of, e.g., chiral sepns. in capillaries. The invention includes the use of binary gradients (chemical and porosity gradients or thermal and porosity gradients) or the simultaneous use of 3 gradients for point mutations having a very high m.p. In the case of **capillary electrophoresis**, the invention extends also to the use of batteries of capillaries, for the simultaneous anal. of a number of samples. Addnl., the invention includes the detection of DNA fragments (or of proteins and other analytes) by laser-induced fluorescence detection and the possibility of operating, in **capillary electrophoresis**, with mixed polymer solns. and with polyacrylamides obtained with monomers highly resistant to hydrolysis.
